CHAPTER III

COMPARABLE ESTIMATES OF WORKFORCE BY DIFFERENT EMPLOYMENT CATEGORIES

1. INTRODUCTION

In the present study, the analysis of workforce is important, at least, for two reasons. Firstly, it examines inter-district variations in productivity which is measured in terms of labour productivity(Chapters IV and VI). Secondly, it considers the industrial structure (employment) of workforce as an indicator of economic development. An attempt is made (later in Chapter V) to isolate and quantify the contribution of industrial structure to the inter-district income inequalities in Karnataka for the years 1960-61 and 1970-71. Such an exercise is meaningful only when the data on workers by employment categories on comparable basis for the periods under consideration are available. Therefore, an accurate measurement of supply of workforce and its changes, in each of the districts, on comparable basis assumes greater significance. But identification and measurement of economically active population is not an easy task. In fact, the measurement of economically-active population involves insurmountable conceptual problems. The comparability of data on workforce and its changes, over the period get complicated with the changes in definitions or concepts of workforce from year to year. The size of the workforce may vary from census to census, due to differences in concepts and definitions or due to differences in actual procedures of data collection. This problem is more serious in the case of female workers. A wide variety of conceptual and procedural changes may be reflected in the movement of female workforce, into and out of workforce, from one census to another.

Concepts and definitions of workforce have undergone changes between the 1961 census and the 1971 census of India . As such, it is necessary to examine in detail the problem of comparability between 1961 and 1971 census economic data. Then, the methodology of adjusting the data of the two censuses on comparable basis has to be evolved. The next section devotes itself to this aspect. In the third section, the workforces in the different industrial categories are estimated for the year 1961 such that they are made comparable to the 1971 census economic data. The fourth section deals with the growth of workforces by sectors between the periods 1961 and 1971. The conclusions are presented at the end.

2. <u>CENSUS DATA ON WORKFORCE</u> : <u>PROBLEM OF COMPARABILITY AND</u> <u>THE ESTIMATES</u>

A closer examination of census economic data by sex reveals that the total workforce in Karnataka State has declined from 1.07 Cr. in 1961 to 1.02 Cr. in 1971 (i.e. about 5 % decline in a decade), whereas the total population of the state has increased at the rate of 2.4 % p. a. during the same period . It is also important to note that, while the male workforce increased slightly, the female workforce declined substantially in all the districts. It is generally believed that the data regarding male workforce are relatively more firm as compared to that of female workers, as the latter are more sensitive to changes in concepts and procedures. In 1971, however, even the figures of the male worker appear to be gross underestimates of the true size of the working force. This is evident when we look at the worker figures of 1961 and 1971 census data which are given in Table 3.1 for the districts of Karnataka. J. Krishnamurthy pointsout that such a large fall in crude rates is unlikely, unless there is a reason to believe that changes in age composition and/or socio-economic factors have operated to lower worker participation.¹ However, the decline in worker participation

retrate partly reflects a change in the concepts. Hence, the examination of differences in the concepts and the definitions in the 1961 and 1971 censuses needs attention. The major differences in the concepts and the definitions used in 1961 and 1971 are as follows :

In 1961 and 1971, the data on workers were i) collected by adopting the labourforce approach i.e., classifying a person according to his status as worker or non-worker on the basis of his participation in economic activity during a specified reference period.² The reference period for the seasonal workers employed in agriculture and household industries was the last working season in 1961 and the last one year in 1971. The reference period for other workers in regular employment was reduced from a fortnight in 1961 to one week in 1971. Because of this difference in reference periods, at the 1961 census, a person was categorised basically as an economically active worker, even if such a person's contribution to work was extremely marginal.³ For example, if a woman who is basically, engaged in household duties, went to her husband's field taking his lunch, and, for

² Government of India, "<u>National Accounts Statistics</u> --<u>Sources and Methods</u>," C.S.O., Ministry of Planning, April 1980, pp 59.

^{3 &}lt;u>Census of India</u> - 1971 , Series No. 14 - Mysore, Part I-A, Vol. II, General Report.

about an hour or so tending the cattle, she was straightaway treated as engaged in cultivation. Similarly, a fulltime student, if he sat for a little time, however short the period might have been, in .his father's shop even on a single day in a fortnight, he was treated as an economically active worker and his basic characteristic as a whole-time student was ignored.

ii) Besides the change in the reference periods the other changes introduced were :

(a) In 1961 there was a simple dichotomous classification for a person to turn himself / herself as a worker or as a non-worker, whereas, in 1971, a person was to be classified in either of the two categories, according to the type of the main activity that the person returns himself / herself as engaged in mostly. In otherwords, at the 1971 census, every individual was first asked to declare his main activity. If the individual was economically active, the was classified as cultivator, agricultural labourer, household industry or as other worker. The classification would depend on the main activity of the person. Persons were also asked if, apart from the main activity, they did any secondary work. If so, they were appropriately categorised in question no.17. This structure emphasises main activity as such. Thus, a woman who is mainly a housewife but works occasionally in the fields to help the family would be recorded as a

'non-worker-housewife', first under question no.16 and her occassional work would be reflected in question no.17 as cultivator or agricultural labour. In otherwords, many persons who were workers only marginally might have been counted as'workers' in 1961 and as 'non-workers' in 1971.

(b) During the 1961 census, data on the secondary activity (or work) of the person were not collected, while in 1971, data on 'secondary' work were collected in respect of both 'workers' and 'non-workers' . "Theoretically speaking, the persons enumerated as workers under question 16 and those with secondary work in question 17 should be comparable with the 1961 results. However, operational deficiencies may have tended to depress the number whose secondary work was regarded. The scale or size of unsuccessful enumeration of question 17 on secondary work is not known. In the 1971 census, family workers, particularly women, who contribute labour in family, cultivation or who work as agricultural labourers in the fields of others for wages occasionally, but who spend their time mostly as housewives are recorded as non-workers. To this extent, family workers who in 1961 census would have been recorded as workers are not enumerated as such in the 1971 census. In such cases, if their contribution has not been recorded as secondary work, the result would tend to depress the number of total workers. This is in contrast to the inflation of

such workers stated to be effect of 1961 census definition."4

Thus, on comparing the two definitions, one gets an impression that the 1961 census had a very generous view of the uconcept. Therefore, many researchers have contended that the 1971 census data and 1961 census data are not strictly comparable. To preserve comparability between the results of two census, the Registrar, General of India conducted a sample survey over the period December 1971 to June 1972 where both the sets of census questions were canvassed. Two inter penetrating sub-samples of households in rural and urban areas were drawn independently on 18 states including the Union Territory of Delhi. The 1971 economic questions were used in one sample and the 1961 questions in the other. In the model of estimation, the 1971 sample participation rate was taken to be equal to the 1961 sample participation rate with three additive components, viz., 1) i) the effect due to conceptual differences ii) the effect due to temporal changes, and iii) the effect of sampling error. As the sample enquiries were conducted under almost similar conditions and the two sub-samples were completely independent in all respects, the net effect of temporal change and the interaction between the conceptual and temporal effects

^{4. &}lt;u>Census of India - 1971</u>, **S**eries No. 14 - Mysore, Part I-A, Vol.II, General Report.

were assumed to be negligible. The sampling error of the interpenetrating sub-samples are also likely to be of the same order. According to Sample Survey, an estimate of the effect of conceptual difference between 1971 and 1961 census participation rates would be given by the difference in the two sample participation rates. Such results for male and female workers in rural and urban areas by three categories of main activity, Viz., Cultivators(C), Agricultural labourers (AL) and Other Workers (OW), are published in the census of India 1971, Report of the Economics Questions -Some Results - Paper I (Registrar General of India, 1974). For arriving at the comparable estimates of number of workers, the sample survey suggests an additive model of adjustment. But, this does not solve the problem of comparability of economic data of Censuses for the districts of Karnataka, because, the survey which was based on two sub-samples suggests the method of deriving comparable data on workforce for the states.

However, the problem of comparability of census economic data between 1961 and 1971 is being solved in several ways. Some of them are ;

i) Adjusting the 1971 workforce to fit the 1961 concept. In this case, age, sex, area specific of 1961 workforce is applied to the 1971 population and the workforce under the

assumption of constancy rate of workforce between the two census/is drawn.⁵

<u>L</u>es

ii) Comparing the economic data of 1961 and 1971 with respect to male worker participation rate without any adjustment, and not including female participation at all.⁶

iii) Some studies have adopted a little modified way of deriving comparable data than the method suggested by sample survey.⁷

iv) There are also studies which have used census data for estimation of workers in the intervening periods without any adjustment on the ground that the differences in concepts will have little effect on the analysis.⁸

- 8 S. K. Mukhopadhyay, "<u>Sources of Variation in Agricultu-</u> ral productivity," The MacMillan Company of India, Ltd., Delhi, 1979, pp 32.

In the present study, an attempt is made to estimate the workers on comparable basis by adjusting the 1961 Census data suitable to the 1971 Census data dimensions. The 1971 Census definition is taken as the base for the present analysis, since, it is considered to be more scientific and acceptable to many researchers. It is assumed that the age-sex specific worker participation rate in each district has remained constant between 1961 and 1971. By applying the age-sex specific worker participation rate of 1971 to the corresponding population category of each district in 1961, the age-sex specific workers in 1961 are obtained. The age-sex specific workers, so derived, are addedup to get the total workers in each district. When the total workers are divided by the total population of the respective district, one can get the overall worker rates in each of the districts for the year 1961. These rates, then, are made comparable to the 1971 Census data. The estimated rates are named as the "Adjusted worker participation rates in 1961."

But, deriving the comparable data on workforce, on the lines of the above methodology, is not simple. This is because, there are differences in the age-groups of workers and population between the two censuses, i.e., 1961 and 1971. Therefore, it is necessary to make some adjustments. The 1971 Census classified the population and workers by sex in

eight broad age groups, viz., 0 - 14, 15 - 19, 20 - 24, 25 - 29, 30 - 39, 40 - 49, 50 - 59 and 60+, besides the category of Age Not Stated (ANS). The 1961 Census classifies the population and workers by sex in four age groups, viz., 0 - 14, 15 - 34, 35 - 39 and 60+, besides ANS . To ensure inter-census uniformity of age groups, the researcher regrouped the population and workers of the 1971 Census data in to three broad age-groups, viz., 0 - 14, 15 - 59 and 60 and above. Then the worker participation rates for the respective age-groups were calculated. After obtaining the age, sex-specific worker participation rates for 1971, the required age, sex-specific of population from the 1961 Census, by regrouping the detailed age groups distinghished by the 1961 Census, were derived. Then by applying the above said methodology, the adjusted worker participation rates for the year 1961 were obtained. This method captures the age-sex composition of populations The estimated (or adjusted) worker participation rates in 1961 and worker participation rates of 1971 Census are given in Table 3.2.

At this stage, it is to be noted to what extent the estimates are underestimated when compared to 1961 actual Census data. The degree of underestimation in respect of female worker is found to be significant in all the districts.

However, the degree of under_estimation, as regards the female workforce, varies from 30.59 % in Dakshina Kannada to 75.48 % in Hassan, whereas the degree of underestimation for male workers varies from 2.50 % in Raichur to 8.64 % in Dakshina Kannada. In fact, the results clearly indicate the extent of over_estimation of female workers by the 1961 Census, which has employed a liberal concept of workforce while that of 1971 Census has not. The degree of underestimation for the total workers varies from low level of 15.40 % in Kodagu to high level of 32.30 % in Tumkur. The degree of underestimation of total workers for Karnataka is worked out at 23.09 %.

A comparision of the estimated (or adjusted) workforce for 1961 and the 1971 Census workforce, reveals that in as many as 13 districts there has been a decline in the worker participation rates in 1971 from 1961. However, there has been an increase in the worker participation rates in Kodagu, D.K., Tumkur, Bengalore, Belgaum and Mysore districts from 1961 to 1971.

3. ESTIMATES OF COMPARABLE WORKFORCE BY EMPLOYMENT CLASSIFICATION : 1961 AND 1971

Changes in the industrial distribution of the workforce are a major indicators of changes in the level of development. Therefore, in order to understand the influence of changes in the industrial structure (employment) of workforce on changes in the level of development, it is necessary that the workforce be classified similarly by the employment categories for the periods of comparision. But, the classification of workers by employment categories in the two Censuses of India i.e., 1961 and 1971 are found to be dissimilar. Hence, an attempt is made in the present section to derive a set of comparable estimates of the structure (employment) of workforce in the districts of Karnataka for the two bench-mark years, viz., 1960-1961 and used 1970-1971.

Although, both the Gensies of India, viz., 1961 and 1971, classified workers in nine broad categories, there is a difference in their classification. The 1961 Census system of industrial classification was based on the Standard Industrial Classification (SIC) of 1960, while the 1971 classification was based on the National Industrial Classification (NIC) of 1970. There are differences between the Standard Industrial Classification of 1960 and the National Industrial Classification of 1970. These differences have to be kept in mind while comparing the economic data of the two Censuses. A comparative Chart of NIC 1970 and SIC 1960 is provided in Appendix Table 3.1. The industrial categories adopted for the 1971

Census, on the basis of NIC 1970 are also indicated in the said Table. In 1971, under Industrial Category V, workers are classified as V(a) if they are workers in manufacturing, processing, servicing or repair establishments, which is not a household industry. Cultivators and Agricultural Labourers are identified separately in the individual slip and therefore, no NIC - 1970 Code was assigned to them.

The classificatory scheme of workers in Industrial Categories at the two Censuses are given in Table 3.3 for easy comparision.

TABLE 3.3 : Industrial Category of 1971 and 1961 Census.

Industrial Category	1971 Census	1961 Census
Cultivators	I	I
Agricultural Labourers	II	II
Livestock, Forestry, Fishing, Hunting, Plantations, Orchards and Allied Activities	3 III	III
Mining and Quarring	IV	III
Manufacturing, Processing, Servicing and Repairs		
(i) Household Industry	V (a)	IV
(ii) Other than Household Industry	V(b)	V
Construction Trade and Commerce Transport, Storage and Communications Other Services	VI VII VIII IX X	VI VII VIII IX X
Non-Workers	Δ	A

Source : <u>Census of India - 1971</u>, Series-14 Mysore, Part 1-A Vol.II, General Report, pp 814. At this stage, the difference between the Industrial Categories adopted at the 1961 and 1971 Censuses may be pointed out. At the 1961 Census, Category III included Livestock, Forestry, Fishing, Hunting, Plantations, Orchards and Allied Activities, with Mining and Quarrying; and Household Industry was separately Categorised as Category IV. At the 1971 Census, Mining and Quarrying has been separated as Category IV and Household Industry has been brought under Category V.

Further, there is an important difference between the type of the activities that are included under household industry in the 1961 Census and those included in the 1971 Census. Household industry includes activities under Division 0 Agriculture, Hunting, Forestry and Fishing and Division 1 Mining and Quarrying of the NIC 1970 along with those under Division 2 and 3 Manufacturing and Repair in the 1961 Census. In the 1971 Census the activities falling under Division 0 and 1 are excluded from household industry and the latter, therefore, only covers those falling under Divisions2 and 3 Manufacturing and Rapair.⁹

^{9 &}lt;u>Census of India - 1971</u>, Series No. 14, Mysore, Part I-A, Vol. II, General Report.

Thus, it is evident that the industrial classification of workers in 1961 is not the same as that of the 1971 Census. However, Table IV Part C of the 1961 Census provides detailed information on the occupational divisions, which in turn, help suitably to adjust the 1961 figures for all ages without recourse to approximation. In fact, it is a sort of reclassification of workers in the Categories III and IV of 1961 Census suitable to the Categories III, IV and V(a) of workers in the 1971 Census. Such a reclassification of workers in 1961, gives comparable classification of workers between the two Censuses.

In 1971, Category III consists of workers In Division 0 fotal (Household + Non household), Category IV Consists of Workers in Division 1 Total (Household + Non household) and Category V(a) consists of workers in Divisions 2 and 3 Total (Household and Non household). In 1961, Category III consists of workers in Division 0 Non Household and Division 1 Non Household and Category IV consists of workers in Division 0 Household, plus Division 1 Household, plus Divisions 2 and 3 Total (Household + Non Household). By clubbing the workers in Division 0 Non Household of Category III and the

¹⁰ Similar reclassification of workers for Indian States was also made. See, R.H.Dholakia, "Inter-State Variations In Economic Growth in India", An unpublished Ph.D. Thesis submitted to M.S.University, Baroda, April 1977, Chapter 4.

workers in Division 0 household of Category IV of the 1961 Census data, the researcher obtained the workers in Category III of 1971 in 1961. By adding workers in Division 1 Non Household of Category III with workers in Division 1 Household of Category IV of 1961, the workers in the Category IV of 1971 in 1961 are obtained . The residual of workers in Divisions 2 and 3 Total of Category IV of 1961 forms workers in Category V(a) of 1971 in 1961. The details of workers, in Divisions 0, 1 and 2 & 3 Household and Non Household, are given in Table B-IV part C of the 1961 Census. The workers in the mine Industrial Categories of 1971 Census and the workers reclassified in nine Industrial Categories (as per the 1971 classification) for 1961 are given in Appendix Table 3.2 and Appendix Table 3.3, respectively.

Now, the task is to calssify the workers into three broad sectors, viz., the Primary Sector which includes agriculture and allied activities, forestry and fishing, the Secondary Sector, that includes mining and quarrying, large-scale and small-scale manufacturing, construction and the Tertiary Sector which comprises electricity, gas and water supply, trade and transport, banking and insurance, public administration and other services. It is easy to distinguish clearly these three sectors from one another

in the 1971 Census classificatory system of workers. The aggregation of I, II and III Industrial Categories of the 1971 Census corresponds to the concept of Primary Sector ; and the aggregation of the Industrial Categories IV, V, VI of the 1971 Census clearly define the Secondary Sector ; and the aggregation of the Industrial Categories VII, VIII and the aggregation of the Industrial Categories VII, VIII and IX as given in the 1971 Census forms the Tertiary Sector for our purpose . Table 3.4 presents the Industrial Structure of the workingforce in these three broad sectors in 1970-71.

From the table, it is very clear that only in Bangalore and D.K. the share of the Primary Sector in the Total employment is less than 60 %. But in all other districts, the share of the Primary Sector in the total employment is above 70 % in 1970-71; and in the districts like Hassan, Tumkur and Mandya it is more than 80 %. On the other hand, the share of the Secondary Sector in the total employment does not exceed 12 % in any of the districts, except in Bangalore, D.K. and Bijapur where it does in 1970-71. In fact, it is found that in Kodagu, Chikmagalur, Hassan, Tumkur, Mandya, Kolar, Raichur and Bidar, the share of the Secondary Sector in the total share of employment is less than 10 % in 1970-71. The the Tertiary Sector in the total employment is less than 20 % in all the districts except Bangalore.

: Workers In Three Broad Industrial Group, Karnataka : 1971. 3.4

TABLE

,

,

Now, the problem which remains to be solved is that of estimation of the industrial structure of the 1961 total adjusted workers (our estimates). The bringing together of workers in to three broad sectors directly from the 1961 Census data prevents the comparision between the industrial structure of workforce into three sectors, in 1961 and that in 1971 for the obvious reason of differences in the concepts used. Hence, there is a need to adjust the workers in the nine categories for the year 1961 based on the concept of the 1971 Census. For the actual 1961 Census economic data, the ratio of workers to total workers for each of the nine categories of workers is, first, worked out. Then the calculated ratios are applied to the total adjusted workers (estimates) of 1961 to obtain the worker figures in each of the nine categories for the year 1961. The worker figures, so derived, in different employment categories are made comparable to those of 1971. This type of adjustment assumes that the degree of underestimation which is worked out for all the workers in each district is spread uniformly in all the categories of workers. The adjusted workers in the nine industrial categories (comparable to industrial classification of 1971) for 1961 are given in Appendix Table 3.4. From the data given in Appendix Table 3.4. it is easy to derive the three sectoral

classification of Adjusted Workers for the year 1961 as was done for the year 1971. The Adjusted Workers in the three broad sectors for 1961, which are made comparable to 1971, are given in Table 3.5.

It is clear from the table that in all the districts except Bangalore, the share of the Primary Sector in the total employment is above 70 % (while in Hassan, Tumkur, Mandya and Kolar it is above 80 %). On the other hand, the share of the Secondary Sector in the total employment does not exceed 20 % in any of the districts in Karnataka in 1961; and is less than 10 % in Kodagu, Chickmagalur, Bellary, Hassan, Tumkur, Mysore, Mandya, Kolar, Raichur, Gulbarga and Bidar. The share of the Tertiary Sector in the total employment does not exceed 20 % in any of the districts, with the exception in Bangalore where it does. It is below 10 % in Hassan, Tumkur, Mandya and Bijapur districts.

It can be observed, from the data given in the two tables, viz., Table 3.4 and 3.5, that in as many as fifteen districts the share of the Primary Sector in the total employment has fallen between 1961 and 1971, whereas, in four districts, viz., Shimoga, U. K., Bellary and Raichur, it has moved up. The share of the Secondary Sector in the total employment has improved from 1961 to 1971 in all the districts, except Shimoga, U.K., Chikmagalur, Dharwad and

Bijapur. Though the share of the Tertiary Sector in the Total employment has improved in almost all the districts, the fall is observed in Shimega, Bellary and Raichur between 1961 and 1971. Thus, despite the changes in the structure of labour force between the two Censuses, it is interesting to observe that more than 71 % of the labour force is employed in the Primary Sector and only 12 % and 17 % are employed in the Secondary and the Tertiary Sectors, respectively, in Karnataka State for the Year 1971. The findings suggest that, the growing population is still absorbed in the Primary Sector which in turn puts further pressure on land. If this tendency is allowed to continue, it may, perhaps, prove to be a major retarding factor in the growth and development of the district economies.

4. GROWTH OF WORKFORCE

The average decadal growth rates of workforce by broad sectors in Karnataka between the years 1961 and 1971 are worked out and given in Table 3.6. From the table it can be observed that the overall growth of workforce ranges from 17.01 % in Kolar to 61 % in Mysore. The decadal growth of workforce is found to be above 20 % in as many as 13 districts.

The growth of workers, in the Primary Sector, varies

,

from 8 % in D. K. to 38 % in Shimoga between 1961 and 1971. It is also observed that the growth of workforce in the Primary Sector is higher than that of the total workforce in Shimoga, Uttar Kannada, Bellary and Raichur during the decade. Apart from these districts, in two more districts, i.e., Chitradurga and Mandya, the growth of workforce in the Primary Sector exceeds 20 %.

The increase in the workforce in the Secondary Sector varies from 2.64 % in U. K. to 86 % in D. K. between 1961 and 1971. It is interesting to observed that the workforce in the Secondary Sector grew by more than double the rate of that of the total workforce in D.K., Hassan, Tumkur, Bengaløre, Kolar and Bidar.

The growth of workforce in the Tertiary Sector varies from 7 % in Bellary to 69 % in Bangalore. The workforce in the Tertiary Sector grew by more than 40 % in eleven districts. However, the growth of workforce in the Tertiary Sector is found to be below the rate of growth of total workforce in Shimoga, Bellary, Mysore and Raichur districts.

5. CONCLUSION

i) The concepts and definitions of workforce have undergone changes between the two Censuses of India i.e.,

1961 and 1971. Therefore the economic data of the 1961 Census and 1971 Census are not strictly comparable. In the present work, the workers are estimated on comparable basis by adjusting the 1961 Census data suitably to the 1971 Census dimensions.

ii) However, the classifications of workers by employment categories in the two Censuses of India i.e., 1961 and 1971 are also found to be dissimilar. With the help of the details on workers, provided in Table B-IV Part C of the 1961 Census, the workers in 1961 are reclassified suitably to the 1971 Census classification of workers. Then, by applying the ratios of nine categories of reclassified workers of the 1961 Census to the total Adjusted workers (estimates) of 1961, the workers in each of the nine categories for the year 1961, which are now made comparable to that of the workers classification found in 1971, are obtained.

iii) Despite the changes in the structure of labour force between the two Censuses of India, it is observed that more than 71 % of the total workforce is employed in the Primary Sector and only 12 % and 17 % are employed in the Secondary and Tertiary Sectors, respectively, in Karnataka State for the year 1971. The results indicate that the increased population between 1961 and 1971 is largely absorbed in the Primary Sector.
