

CHAPTER VI

Summary And Conclusions

This study is aimed at the exploration of the pattern of agricultural wage movements over the period among the villages and districts of Rajasthan. The study enquires into the nature and the magnitude of inter-temporal, inter-regional and inter-operation wage variations in agricultural sector. And also examines wage variations over seasonal cycles. An important aspect of the study pertains to the examination of relative movements between wages and cereal prices. Like-wise, movements of agricultural productivity and those of real wage rates have also been analysed. Lastly, it investigates into the influence of certain economic and socio-demographic parameters on wage rates through a regression analysis based on cross-section data.

The study is based on agricultural wage data relating to 48 villages spread over all the twenty six districts of Rajasthan. It covers a period of 12 years from 1967-68 to 1978-79. Wages paid to adult male casual labour for each of the six major operations, viz. ploughing, sowing, weeding, transplanting, irrigation and reaping and harvesting have been examined and analysed. The study excludes wages paid to female and child labour.

Requisite wage data are compiled from the office records of the Directorate of Economics and Statistics, Rajasthan, Jaipur. The gist of the present study is recapitulated in the pages below.

Consistently rising trend was observed in money wage rates. Wage increases were significant over the period under study in initially low wage villages; and moderate in initially high wage villages. As such, wages converged over the period. Highest rises were observed in the year 1975-76. The averages over the quartiles also showed an upward trend with varied rates. Rate of increase varied among the villages every year. Consequently, ranking structure of the villages had undergone a change frequently.

In real wages too, the general trend was upward, though not steady. About 70 percent of the villages under study showed a fall in their real wage rates during the year 1974-75, the year of the highest rise in the cost of living of agricultural labourers in Rajasthan. This follows from the above that money wage increases were not sufficient to off-set the adverse effect of price rises during this year.

Significant inter-village^{and} inter-district wage differentials continued to exist throughout the period under study.

Analysis of relative movements of wage rates and cereal prices showed that wages adjusted to changes in prices with a lag of a year or so.

Movements in prices were sharper and frequent; while, those in wages were mild and less frequent. Inverse relationship was marked between wage fluctuations and irrigation intensity. Wage fluctuations were sharper in desert and unirrigated areas as compared to the highly irrigated areas. Similarly, wage rates varied sharply, where agricultural activities were confined to a single and limited number of crops over a year. Increases and decreases both were higher in prices than in wages; while, increases were found to be higher than decreases in wages. Thus, it seems, wages remained stickier towards falls than towards rises in the short period.

Seasonality and nature of the work in agriculture resulted in considerable differentials in wage rates of various operations. Ploughing, a strenuous work and mainly reserved for adult males, had the highest wage rate over the entire period under study. On the other hand, operations of general nature like weeding and transplanting where women and children also participate, could command only low wage rates.

Absolute wage variation between operationwise wage rates widened over the period, while the ratio between the

operations with highest and lowest wage rates declined over the years.

Wage variations were high between the villages in Rajasthan, and these variations showed frequent changes and erratic behaviour. The ratio of the highest wage village to the lowest wage village showed a slightly declining trend over the entire period under study; while the coefficient of variation showed a mildly rising trend.

Impact of irrigation on spatial wage differentials was distinctly marked. Spatial variations were high in desert and low irrigated regions, and low in the highly irrigated regions. The distribution of irrigation potential among the villages of a region had played a decisive role in determining the magnitude of spatial wage differentials.

Since seasonality is inevitable in agriculture, wages are expected to fluctuate between slack and busy months depending upon the degree of variation in labour demand. Wage differentials were higher during the slack months as compared to the busy months of October to December. But July showed very high wage variations. Since July is the busiest month, wage variations are expected to be lower. But the results are contrary. This suggests that the degree of temporal wage differentials in July month would have depended upon the land-man ratio, size and distribution of operational holdings, the degree of tractorisation etc.

Unsystematic and highly fluctuating seasonal differentials did appear over period in almost all the villages. No trend seems to be established. Since irrigation increases agricultural activities and spreads them evenly round the year, wages varied mildly between months in highly irrigated villages. But at the same time, in many of the highly irrigated villages, temporal wage differentials were high and inconsistent with the above reasoning. It seems intensity of seasonal variations would have depended not only on irrigation, but on other natural factors also.

Results of analysis of variance do indicate that seasonal variations were highly significant between villages from 1968-69 to 78-79 implying that seasonal wages differed significantly from village to village. But among the months, seasonal variations were significant in most of the years implying that labour supply curve would have been upward sloping rather than horizontal. This further suggests that wages were demand elastic.

Graphical examination of temporal wage variations reveals that these were high and by and large, identical in their month to month movements over the years. The intensity of fluctuations was also found similar.

The analysis of irrigation based classification of villages suggests that temporal wage variations largely

depended on the intensity of irrigation. Intensity of irrigation and the intensity of seasonal wage fluctuations were found to be inversely associated.

The analysis further highlights that there existed a pronounced wage cycle in seasonal wage movements over a year. Wages touched peak in July, November, April, May and June; trough in September, January and February. Wages receded in August and December and recovered in October and March. As such July, November, April, May and June were found to be the months of the highest agricultural wage rates; while, September, January, and February were the months of the lowest wage rates. August, October, December and March were found to be the months of the moderate wage rates.

The general pattern of operation-wise wage differentials within a village seemed to be declining over the period. But in many of the highly irrigated villages, operation-wise wage variations expanded over the period. The reason seems to be the degree of substitution of labour. Mechanisation of certain operations would have caused a fall in the demand of those operations, and consequently a decline in wages.

Operation-wise wage differentials between villages were also found to be highly significant as seen from variance analysis.

Real wage rates were found to be positively associated with the productivity per hectare (a demand affecting factor) in 19 out of 20 districts over a stretch of 12 years. But statistically significant relationships between the two, existed only in 9 districts. Real wage rates did vary when productivity varied.

The level of significant relative movements between wage rates and productivity seems to be directly related with the level of irrigation potential.

Fluctuations are found to be steeper in productivity than the fluctuations in real wage rates. Further, the fluctuations in wages and productivity are smooth in intensively irrigated regions; while sharper in comparatively low irrigated regions.

Productivity per hectare and real wage rates in agriculture have shown an over all rising pattern over the period. Particularly, sharp increases are noticed during the recent years.

Wage rates for various operations are found to be directly associated with the total production. Production influenced wage rates for various operations uniformly. But to some extent, harvesting wage rates seem to be more sensitive to production.

Of the nine selected explanatory variables, six have shown expected relationships with the explained variable, the wage rate. Land-man ratio showed positive and highly significant relationship with wage rate. Presence of more of female labourers and more of Scheduled Caste and Scheduled Tribe population has a depressing effect on the wages.

Composite index of location and communication scores appeared to effect wages moderately, while, individual segments of the composite index, such as distance from the nearest town or means of transportation, did not show any relationship with wages.

Insignificant correlation between wage rate and percentage of agricultural labourers to all agricultural workers would have been due to improper definitional concepts adopted in 1971 census for the enumeration of working population.

Unexpected reverse response of wage rate to the variation in cropping intensity^{or} in non food crops or in percentage gross irrigated area may be attributed to very low increase in irrigated area in comparison to gross sown area, its unequal distribution, very small size of operational holdings, larger family size of cultivators, heavy influx of labourers from the nearby regions etc.

After detecting cases of multicollinearity with the help of correlation matrix, four independent variables are selected for regression analysis. Land-man ratio explained wage variations most and affected wage level significantly in

positive direction) while, low caste population (S/C & S/T) depressed wage level considerably. Remaining two variables (agricultural labourers and location communication scores) influenced wages in expected direction gently. Of the total spatial variation in wages, 24% wage variation was explained by the variables included in the model jointly. Since the F-ratio was significant at 5% level of confidence, it seems that variables included in the model are important.

Another regression equation was also fitted after replacing agricultural labourers by sex-ratio, and keeping the other three variables unchanged. With the inclusion of sex-ratio, low caste population did not depress wages significantly. Similarly, the importance of land-man ratio in influencing wage level also declined. But value of R^2 and significance level of F-ratio increased. Total wage variation explained by the model was 28 percent. F-ratio was found to be significant at 1% level. 'd' statistic (Durbin-Watson Statistic) also suggested that there did not exist auto-correlation.

Regression Equation fitted in log-linear form has slightly improved the value of R^2 . Level of significance of various explanatory variables changed considerably. Sex and Caste factors played crucial role in affecting wage level and in explaining wage variation in agriculture. Elasticity of agricultural wage rate with respect to changes in sex ratio

is -0.68. Sex-ratio depresses the wage rate most.

Results of the study suggest that the factors that may have determined the wage level and explained wage variations at village as well as at district levels had been, by and large, homogeneous. Variables included in the district level regression model, explained 50% of the total existing variation in wages. F-ratio was significant at 1% level of confidence. Land-man ratio and sex-ratio explained geographical wage variations most among the districts and also among the villages. Low impact of land-productivity on agricultural wages as compared to that of land-man ratio does indicate that volume of work rather than value of product, plays crucial role in deciding wage rates in agriculture.

The analysis further shows that geographical wage differentials in agriculture are, by and large, equally based on variations in factor productivity and also on variations in labour force composition.

APPENDIX TABLE

Basic wage data, compiled from the office of the Directorate of Economics and Statistics Rajasthan, Jaipur, for the period 1967-68 to 1978-79, are presented in Appendix Table. Since the present study is confined to the wage rates paid to the adult male casual labour in agriculture for the six major operations only, we have classified the data by operation, village (wage reporting centre), month and the year. Abbreviated terms used to facilitate the presentation of the data are explained as under:

- i) 'Opr' denotes Operation;
- ii) 'P' stands for Ploughing;
- iii) 'S' represents Sowing;
- iv) 'W' means Weeding;
- v) 'I' refers to Irrigation and Allied Activities;
- vi) 'R and H' stands for Reaping and Harvesting;
- vii) 'T' represents Transplanting.
- viii) '___' indicates either the wage rate was not reported by the wage reporting agency; or the labour was not engaged for the particular operation during the reference month;
- ix) 'F' shows famine in the area.

Row-wise data show wage rates for the particular operation in various months; while, column-wise data represent wage rates for different operations in a month.
