

Chapter IV

RESULTS AND DISCUSSION (Contd.)

Part II

OTHER PHYSICAL MEASUREMENTS

The preceding Part I has been devoted to the discussion of results pertaining to two main aspects of physical growth, viz. weight and height, regarding which sufficient research studies have been made especially in the west, though very few systematic ones in India. The present part II deals with findings on other aspects of physical growth, as referred to in the beginning. Hardly a few studies (particularly in Gujarat) have been made in this respect. Much information based on statistical analysis of data on these aspects of measurements as related to a number of variables can be studied and included here, but only the most relevant part is discussed briefly in this chapter owing to limitations of space and nature of work for a thesis like this; the rest will form a follow-up work in other subsequent studies. The investigator has not been able to go through advanced statistical analysis in these cases, though an attempt is made to submit a general view of findings on these aspects of growth through a summary of tables and figures wherever possible. All data of children from 2 to 6 years on these remaining aspects of physical growth at 17 age-points at interval of 3 months

(5699 children) as well at 5 main age levels at interval of one year (1692 children) have been summarized, tabulated and analysed.

3. HEAD CIRCUMFERENCE

As presented earlier, the data on head circumference of 5699 children at 17 age-points as well as of 1692 children at five main age levels of 2, 3, 4, 5 and 6 years, consisting of both boys and girls from urban and rural areas, of five different socio-economic levels, have been analysed statistically and the results have been summarized in tables 4.21_A and illustrated graphically in figures 4.21 to 4.24 below. The head circumference was measured in cms. as explained in the beginning and the general picture of these measures of all children is represented in table 4.21 which summarizes the means and standard deviation of observations on 5699 children at each of 17 age-points, sex-wise and area-wise. Figure 4.21_A illustrates the same along with increase at each successive age-point represented by histograms showing absolute increases from the original base at first age-point of two years, and the relative increase or decrease from just the preceding age-point being shown by the velocity curve.

It is seen from results in table 4.21 that head circumference on the whole goes on increasing from 46.60 cms. at 2 years of age to 49.68 at age of 6 years, and the increase is almost linear as seen in fig. 4.21, though not consistently uniform. These data

were subjected to statistical analysis by t-test to study significance of differences in means due to sex and area of residence. These results are summarized in table 4.22(i) for sex differences and table 4.22(ii) for area differences.

Table 4.22

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693	15.2785	Beyond .01
M	49.003	48.198		
SD	2.008	1.963		
(ii) Area:	Urban	Rural	t-value	Significance
N	4766	933		
M	48.667	48.395	3.7655	Beyond .01
SD	2.111	1.499		

It is observed from the results in table 4.22 that both the sex as well as area of residence played a significant role in contributing to the growth in head circumference; boys showed significantly higher growth (49.003 cms.) than girls (48.198 cms.) and similarly urban children showed on an average higher growth (48.667 cms.) than girls (48.395 cms.), and these differences were statistically significant.

Next, the data of 1692 children of five main age levels at

2, 3, 4, 5 and 6 years were separately summarized for comparison, and these are represented in tables 4.23 (i) to 4.23 (v) (area x sex-wise) for each of five age levels, and illustrated in figures 4.22 for area and 4.23 for sex. Same trend of differences in sex and area groups is observed also at these five age levels.

Further, the data of boys and girls at each of 5 main age levels were classified according to five socio-economic levels, in order to observe the effect of socio-economic status on growth of head circumference. These data are summarized in table 4.24 on the whole for 5 age levels and in tables 4.24 (i) to 4.24 (v) (socio-economic level x sex-wise) for each of five age levels. The growth at each of 5 age levels for SE level is illustrated in fig. 4.24 along with successive increase by means of histograms.

It would be seen from tables 4.24 as well as 4.24 (i to v) that head circumference on the average increases not only with increasing age, but there is a trend for it to increase with increasing socio-economic level on the whole as well as separately in case of boys and girls.

4. CHEST CIRCUMFERENCE

Data (means, ^{and} SDS and ~~increasem~~) on measurement of chest circumference in cms. on all 5699 children at each of 17 age-points are summarized in table 4.25, area-wise and sex-wise and

illustrated graphically in fig. 4.25.

It is seen from these data that chest circumference on the whole beginning with 46.54 and at age of 2.0 years goes on increasing upto 52.24 cms. at age of 6-0 years, and the increase does not seem uniform. These data were subjected to t-test to examine the significance of the influence of sex and area of residence. These results are summarized in table 4.26 (i) & (ii) for sex and area respectively.

Table 4.26

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	50.785	49.614	16.0279	Beyond .01
SD	2.844	2.649		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	50.311	49.826	4.8210	Beyond .01
SD	2.888	2.364		

It is revealed from results in table 4.26 that both sex and area of residence are significant factors contributing to the growth of chest. Boys showed on an average significantly broader chest (50.785 cms.) than girls (49.614 cms.); and urban

children significantly more (50.311 cms.) than rural children (49.824 cms.).

Further, the data of 1692 children at five main age levels have been summarized for comparison and represented in table 4.27 (i to v) area x sex-wise at each of age levels, and graphically illustrated in figures 4.26 for area and 4.27 for sex and area groups is observed at these five age levels.

Finally, data of boys and girls at each of five main age-levels were split up according to five socio-economic levels studied, and are summarized in table 4.28 on the whole at 4.28(i) to 4.28(v) (SE x sex-wise) separately for each of five age levels, and graphically represented in fig. 4.28.

It would be observed from table 4.28 that chest circumference increases with increase in upto SE_4 , but a slight decrease at SE_5 level at all age levels, except in case of age of 4 years where there is continuous increase upto SE_5 .

5. SHOULDER WIDTH

As above, data on shoulder width in cms. were tabulated and analysed. Table 4.29 and fig. 4.29 represent the means of shoulder width of 5699 children, both boys and girls, urban and rural, at each of 17 age-points from 2 years to 6 years at interval of three months.

It would be seen from these data that shoulder width on the whole increases from 21.07 cms. at 2 years to 26.80 cms. at 6 years with a average of about .3 cm. per age-point or 1.0 cm. per year though not uniformly. These data were subjected to statistical analysis by applying t-test in order to examine the sex and area differences in growth in shoulder width. The results are summarized in table 4.30.

Table 4.30

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	25.038	24.921	3.2040	Beyond .05
SD	2.001	1.920		
(ii) Area :	Urban	Rural	t-value	Significance
N	4366	933		
M	24.798	24.762	3.3538	Beyond .01
SD	2.008	1.715		

It is seen from results in table 4.30 that boys had a significantly higher shoulder width (25.038 cms.) than girls (24.921 cms.), and urban more (24.798 cms.) than rural (24.762 cms.).

Next, same data for 1692 children at main five age levels from 2 years to 6 years at interval of one year were separately tabulated for comparison and are represented in table 4.31 (i to v) area x sex-wise for each age level and illustrated in fig. 4.30

for area and 4.31 for sex. Same trend of differences is observed.

Finally, the data of 1692 children, boys and girls, at each of five main age-levels were tabulated according to five socio-economic levels studied, and are summarized in table 4.32 on the whole, and in tables 4.32 (i to v) SE x -sex-wise separately for each age level, and graphically represented in figure. 4.32.

It would be observed from table 4.32 that shoulder width usually increases with increase in SE level upto SE_4 , but a slight decrease at SE_5 at all age levels except in children of four and five years, who show continuous increase upto SE_5 .

6. ARM LENGTH

Next, data on arm length in cms. were classified and analysed statistically. Table 4.33 summarizes the means, SD, etc. of arm length (area x sex-wise) of 5699 children at each of 17 age-points, and these are graphically illustrated in fig. 4.33.

It would be seen from table 4.33 that arm length on the whole increases from 34.99 cms. at age of 2 years to 47.71 cms. at age of 6 years with an uneven rate of increase. These data were subjected to t-test to examine sex and area differences in growth of arm length. Table 4.34 summarizes the results of the t-test.

Table 4.34 (arm length)

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	43.639	42.806	8.1970	Beyond .01
SD	3.907	3.745		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	43.296	43.001	2.1237	at .05 level
SD	3.821	4.009		

It is apparent from table 4.34 that both sex and area of residence played a significant role in growth of arms length beyond .01 and at .05 level of significance. Boys had more arm length (43.639 cms.) than girls (42.806 cms.); and urban children had more (43.296 cms.) and rural children (43.001 cms.).

Next, the data of 1692 children at 5 main age levels were classified and are represented in table 4.35 (i to v) for each age level (area x sex), and in figures 4.34 for area and 4.35 for sex. Same trend of growth is observed.

Finally, same data of 1692 children were classified according to socio-economic level and are represented in table 4.36 on the whole and 4.36 (i to v) separately for each age level, and graphically in fig. 4.36.

It is again seen from table 4.36 that arm length too increases with increase in SE level at each age level.

7. SITTING HEIGHT

The sitting height for each child was obtained in terms of cms. These data of 5699 children at 17 age-points are summarized in table 4.37 and illustrated in fig. 4.37.

It would be observed from table 4.37 that sitting height goes on increasing with age, from 46.51 cms. at 2 years to 58.73 cms. at 6 years, at uneven rate. These data were subjected to t-test to study the significance of difference between means of sex and area. The results are summarized in table 4.38.

Table 4.38

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	54.531	53.593	8.4236	Beyond .01
- SD	4.200	4.981		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	53.994	54.564	3.7690	Beyond .01
SD	4.2661	4.003		

Results in table 4.38 reveal significant sex as well as

area differences. As usual, boys had more sitting height (54.531 cms.) than girls (53.593 cms.); however in contrast to all measures, the rural children had significantly more sitting height (54.564 cms.) than urban children (53.994 cms.); in other words, the rural children had longer trunk part in comparison to lower limbs, since urban children were found taller on the whole, as seen from table 4.21 earlier.

Next, the data of 1692 children at main five age levels have been summarized in table 4.39 (i to v) area x sex-wise separately for each age level and illustrated in fig. 4.38 for area and fig. 4.39 for sex. Same trend of differences as in table 4.37 is observed also in table 4.39.

Finally, the same data of 1692 children have been rearranged to observe the effect, if any, of socio-economic level. These data ^{are} summarized in table 4.40 on the whole, and in tables 4.40 (i to v) for each age level. All these are graphically shown in fig. 4.40.

It would be observed from results in table 4.40 that mostly sitting height increases also with increase in SE level at each age level.

8. UPPER ARM CIRCUMFERENCE

Data on upper arm measurements (in cms.) of 5699 children at 17 age-points have been tabulated in table 4.41 and graphically represented in fig. 4.41.

The table 4.41 shows that upper arm circumference increases on the whole with increase in age, thus from 13.77 cms. at age of 2 years to 15.07 cms. at age of 6 years, with slight increases at each interval. These data were subjected to t-test to examine the significance of sex and area differences. The results are summarized in table 4.42.

Table 4.42

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	14.712	14.730	0.4594	Not significant
SD	1.557	1.489		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	14.784	14.394	7.1801	Beyond .01
SD	1.549	1.361		

Results revealed that there were no sex differences in upper arm circumference; strangely yet, the girls tended to have larger upper arm circumference (14.730 cms.) than boys (14.712 cms.). However, as usual, area of residence was a significant factor; urban showing higher figure (14.784 cms.) than rural children (14.394 cms.).

Next, the data of 1692 children at five main age levels were examined. These are represented in table 4.43 (i to v) area x sex-wise for each of five age levels, and graphically in fig. 4.42 for area and fig. 4.43 for sex. Same trend of differences is observed.

Finally, same data have been classified according to five socio-economic levels^S, tabulated on the whole in table 4.44 and separately for each age level, SE x sex, in tables 4.44 (i to v); and graphically represented in fig. 4.44.

It would be marked from table 4.44 that upper arm circumference also increases with increase in SE level at each age.

9. FORE-ARM CIRCUMFERENCE

The data on fore-arm circumference in cms. for 5699 children at 17 age-points have been classified and presented in table 4.45 area x sex-wise and represented graphically in fig. 4.45.

The table 4.45 shows that fore-arm circumference increases with increase in age, beginning with 13.79 cms. at 2 years of age to 15.48 cms. at 6 years of age, almost similar to the growth of upper arm circumference; fore-arm circumference to some extent seems to be ^a little more than upper arm circumference.

These data were tested by application of t-test to study the influence of sex and area of residence. The results are summarized in table 4.46.

Table 4.46

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	15.091	14.901	5.2579	Beyond .01
SD	1.216	1.505		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	15.045	14.772	5.3943	Beyond .01
SD	1.430	0.955		

It is seen that there are significant sex as well as area differences in growth of fore-arm circumference. Boys had a significantly greater measure of fore-arm (15.091 cms.) than girls (14.901 cms.), and urban had greater measure (15.045 cms.) than rural (14.772 cms.). In all cases, fore-arm circumference was observed to be greater than upper arm circumference.

Next, the same data of 1692 children at five main age levels have been represented in table 4.47 (i to v) area x sex-wise for each age level, and in fig. 4.46 for area and fig. 4.47 for sex.

The general trend of growth (table 4.47 and fig. 4.46 & 4.47), represented at five main age levels, ignoring the in-between

three-monthly points, remains almost the same as that in the continuous growth observed at all seventeen age-points shown in table 4.45 and fig. 4.45.

Finally, the same data of 1692 children were classified according to socio-economic level, and have been represented in table 4.48 on the whole as well as separately in tables 4.48 (i to v) for each age level, and illustrated in fig. 4.48.

Again, the table 4.48 reveals that the fore-arm circumference usually increases with increase in socio-economic level especially at 4 and 5 years. In all cases, the data in the sub-cells at age of 2, 3 and 6 years in respect of socio-economic level is also small that it is inadequate to draw reliable statistical inferences though there is a trend for each aspect of physical growth to increase with increase in SE level.

10. THIGH CIRCUMFERENCE

With the same procedure, data on thigh circumference in cms. for 5699 children at 17 age-points have been tabulated in table 4.49 and represented graphically in fig. 4.49.

It is seen from table 4.49 that thigh circumference increases with age from 25.35 cms. at 2 years of age to 30.25 cms. at 6 years of age, with somewhat uneven rate of increase. These data were subjected to t-test in order to test the significance of difference between means of sex as well as area in growth of

thigh circumference. The results have been summarized in table 4.50.

Table 4.50

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	28.354	29.029	10.3770	Beyond .01
SD	2.322	2.587		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	28.790	28.072	8.1478	Beyond .01
SD	2.514	2.173		

It is observed from results in table 4.50 that both sex and area of residence had a significant role in growth of thigh circumference. Again, in contrast to other measures, the girls scored significantly higher (29.029 cms.) than boys (28.354 cms.) on thigh circumference, just as on upper arm circumference. This is a significant feature of growth to be noted. As far as area differences were concerned, here too, the urban children scored significantly higher (28.790 cms.) than the rural children (28.072 cms.).

Next, the same data of 1692 children at five main age levels

have been tabulated in table 4.51 (i to v) area x sex-wise for each age level and represented in fig. 4.50 for area and fig. 4.51 for sex. Same trend of growth is observed.

Finally, the data of 1692 children at five main age levels according to socio-economic level have been tabulated in table 4.52 on the whole, and separately for each age level in tables 4.52 (i to v), and represented graphically in fig. 4.52.

As usual, the thigh circumference too has been found to increase with increase in SE level at each age level with a slight decrease at SE_5 in case of 2 and 6 year old children.

11. CALF CIRCUMFERENCE

As usual, the calf circumference was measured in terms of cms. in case of all 5699 children, and the means and SDs of these children at each of 17 age-points have been summarized in table 4.53 area x sex-wise and graphically represented in fig. 4.53.

It would be seen from table 4.53 that calf circumference increases with increase in age from 17.32 cms. at 2-0 years of age to 20.38 cms. at 6-0 years of age, with somewhat higher increase in earlier years and slower in later period. These data were analysed statistically by t-test to examine the influence of sex and area variables, and the results are summarized in table 4.54.

Table 4.54 (calf circumference)

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	19.502	19.372	2.3149	Significant at .05.
SD	2.032	2.216		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	19.564	18.803	10.0816	Beyond .01
SD	2.225	1.383		

It is seen from table 4.54 that sex was a significant factor at .05 level of confidence and area was significant beyond .01 level of confidence. Boys had a larger calf circumference (19.502 cms.) than girls (19.372 cms.), and urban larger (19.564 cms.) than rural (18.803 cms.).

Next, the same of 1692 children at five main age levels have been tabulated area x sex-wise in table 4.55 (i to v) for each age level, and represented graphically in fig. 4.54 for area and fig. 4.55 for sex.

The results in table 4.55 and fig. 4.54 & 4.55 show the same trend as that in table 4.53 & fig. 4.53.

Next, the same data of 1692 children at 5 age levels were classified according to socio-economic level, and are represented in table 4.56, on the whole, in tables 4.56 (i to v) separately for each age level, and graphically in fig. 4.56.

It is again seen from table 4.56 that calf circumference too increases with increase in SE level generally at each age level, though a slight decrease is observed at SE_5 in case of children of 2 years, 3 years and 6 years, perhaps due to insufficient number of observations in those cells.

12. FOOT LENGTH

Again, following the same procedure of analysis, the data of 5699 children at each of 17 age-points for foot length measured in cms. have been tabulated in table 4.57 and represented graphically in fig. 4.57.

The data in table 4.57 show that foot length increases with increase in age, from 13.24 cms. at 2 years of age to 17.71 cms. at age of 6 years, with almost uniform rate of increase. These data were further analysed statistically by means of t-test to examine the influence of sex and area variables on growth of foot length. Results of t-test have been summarized in table 4.58.

Table 4.58

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	16.333	15.987	7.7661	Beyond .01
SD	1.665	1.694		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	16.241	15.794	7.3750	Beyond .01
SD	1.757	1.334		

It is clear from table 4.58 that both sex and area influenced significantly in growth of foot length. Boys had a significantly longer foot (16.333 cms.) than girls (15.987 cms.) and urban children had longer foot (16.241 cms.) than rural children (15.794 cms.).

Next, for purpose of comparison, the data of 1692 children at five main age levels were separated out and represented in table 4.59 (i to v) for each age level, and graphically in fig. 4.58 for area and fig. 4.59 for sex. The trend of growth remains the same.

Finally, data of 1692 children of 5 age levels were tabulated according to socio-economic level and are represented

in table 4.60 on the whole as well as separately for each age level in tables 4.60 (i to v), (SE x sex-wise) and graphically in fig. 4.60.

It would be seen from table 4.60 that foot length mostly increases with increase in SE level.

13. LOWER LIMB (LEG) LENGTH

It would be recalled from earlier discussion on procedure of various measures of physical growth described in Chapter III that lower limb or leg length was not directly measured, but was derived by subtracting sitting height from total height already measured directly. These data on means, SDs, etc. of leg length of 5699 children at each of 17 age-points from 2 years to 6 years at interval of three months have been summarized in table 4.61 (area x sex-wise) and represented graphically in fig. 4.61.

It would be observed from results in table 4.61 that the leg length too increases with increase in age, from 33.49 at 2 years to 48.60 at 6 years of age, with somewhat uneven rate of increase, strikingly highest (3.5 cms.) being at 3-3 years, next best (2.3 cms.) at 4-0 years, 1.9 cms. at 2-6 years and remaining almost about 1.0 cm. at other age-points. These data were analysed statistically by means of t-test to study

sex and area differences in growth of leg length. The results are summarized in table 4.62.

Table 4.62

(i) Sex :	Boys	Girls	t-value	Significance
N	3006	2693		
M	44.343	43.709	1.3300	Not significant
SD	20.342	14.854		
(ii) Area :	Urban	Rural	t-value	Significance
N	4766	933		
M	44.435	42.035	3.7359	Significant Beyond .05.
SD	1.951	4.634		

It would be seen from results in table 4.62 that sex variable did not play any significant role in growth of leg length, though boys tended to have somewhat longer leg (44.343 cms.) than girls (43.709 cms.). However, urban children had significantly longer leg (44.435 cms.) than rural children (42.035 cms.).

Next, the same data of 1692 children at five main age levels from 2 to 6 years at interval of one year have been tabulated in tables 4.63 (i to v) and graphically in fig. 4.62 for area and fig. 4.63 for sex. The trend of growth remains the same.

194

194

Finally, the same data of 1692 children at five age levels have been tabulated according to socio-economic level in table 4.64 on the whole, and separately for each age level in tables 4.64 (i to v) SE x sex-wise, and represented in fig. 4.64.

It would be again seen from table 4.64 that leg length generally increases with increase in SE level, particularly at age of 4, 5 and 6 years; there is some increase at SE_2 and then decrease in case of children of 2 years, and similarly there is some decrease at SE_2 and then increase in case of children of 3 years, all these perhaps due to inadequate number of observations in these cells.

This completes the discussion on various other measures of physical growth.

General comments :

For all parameters (except upper-arm and thigh circumferences) the boys show consistently higher values at all age-points.

This finding is consistent with the general observation regarding the sex-differences in growth (Hurlock, 1964).

As regards the upper arm the boys show larger growth from 2 years to 3 years and 3 months when the girls tend to overtake the boys which they do at the age point 3 years - 9 months (Fig. 4.2(b)) after which the girls have larger circumference upto the age point 5 years - 6 months. Again the growth curves for boys and girls meet at the age point 5 years - 9 months after which the boys tend to outgrow the girls.

The upper arm circumference has been suggested as a visible index of protein-calorie nutrition (Jelliffe and Jelliffe, 1969; Jelliffe and Patrice, 1969). According to this criterion the boys show more marked protein-calorie malnutrition from the age point 3 years - 6 months to the age point 5 years - 6 months. As no parental preference for girls to boys is expected, this may be reflecting the physiological superiority of girls over boys in utilizing the available nutrition.

The same growth trends for boys and girls are seen

^{149 (ii) after p. 256}

in case of the thigh (Fig. 4.2 ~~(j)~~). Here the girls show distinct superiority over boys from the age point 3 years-6 months onwards throughout the age-range under investigation.

Sitting Height

The data on children of 4 years or older are more reliable than for the younger children as the latter do not often follow instructions to sit straight while being measured.

Area (Milieu) differences. (Fig. 4.3 ~~to m~~) ^{4.62}.

In general the urban children show superiority in growth over the rural children. This superiority begins to be prominent by the time the child reaches the age point 3 years-6 months and for all parameters the city children show distinctly superior growth from the age-point 4 years onwards. The head circumference is an apparent exception, but here also (Fig. 4.1 (c)) the differences are small and the slight superiority seen for the rural children may be due to the state and quantity of hair on the head as the head measurement was taken with the hair. The data on head circumference in this study suffer from the fact that measurements had to be taken with hair on the head.

Socio-economic levels and growth.

The samples for socio-economic level 5 (SE 5) were too

small for the investigator to draw valid statistical inferences. The children belonging to socio-economic level 4 (professionals like doctors and lawyers, senior officers, professors etc.) showed consistently superior growth at all age-levels for all parameters under investigations.

The socio-economic level 4 includes people who are well-educated. Of all the lots, they generally do not depend upon hereditary wealth for their status. They are expected to be more particular and careful for the proper development of their children and at the same time have the adequate means to realize their expectations. Perhaps, parents of highest socio-economical status (SE 5) seem to be less careful than those of SE 4, though expected; it may be their negligence or more busy indulgence in their other dealings, or even their assumption that things are taken care of in view of their wealth and status; it may be even due to inadequate number of sample in SE 5.

The I.C.M.R. study does not include Bengal, Bihar and Gujarat. Hence there is need for investigations to establish regional norms for these areas. In the I.C.M.R. study the mean values of height and weight of children belonging to different states were found to be significantly different from one another, which fact also makes it imperative to plan regional studies.

The present investigation is the most extensive investigation in Gujarat undertaken so far and it includes more parameters of growth than any investigation reported so far. Its findings may be utilized for fixing the regional norms for Gujarat for the pre-school-age children (2 years to 6 years). It is suggested that the parameters of growth found for the SE 4 children be accepted as norms for pre-school children of Gujarat. These norms can be revised later in light of more extensive investigations.
